

# Viral Suppression in SHIV-infected Rhesus Macaques following AAV-mediated Delivery of Closer-to-germline Monoclonal Antibodies

Jose Martinez-Navio

Research Assistant Professor

Department of Pathology and Laboratory Medicine

University of Miami - Miller School of Medicine

## COMMUNITY SUMMARY

- **Background:** Delivery of potent and broadly neutralizing antibodies by means of a viral vector (adeno-associated virus or AAV) is a promising approach for both, the prevention and treatment of HIV infection. However, when the AAV-delivered antibodies are seen as ‘non-self’, unwanted host antibodies are raised against them, which can compromise their efficacy by reducing their concentration and functionality.
- **Key question:** Can we overcome this critical issue by using ‘more-self’ antibodies?
- **Key finding:** The use of naturally ‘more-self’ antibodies may be a viable strategy for overcoming the ‘foreignness’ problem and make the AAV-mediated delivery of antibodies more consistent.

# Adeno-Associated Virus (AAV) as a delivery vehicle of broadly neutralizing antibodies against HIV

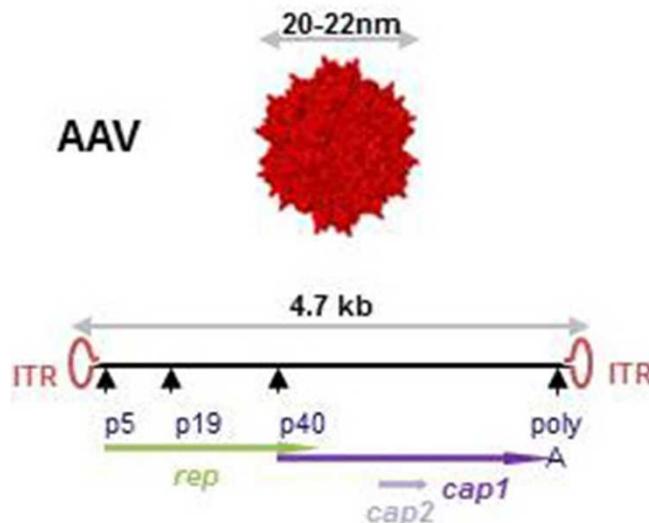

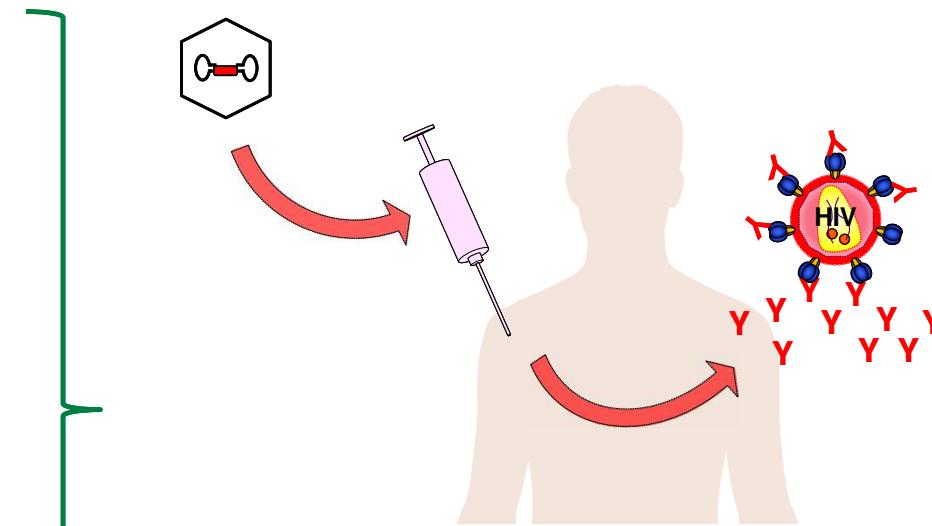

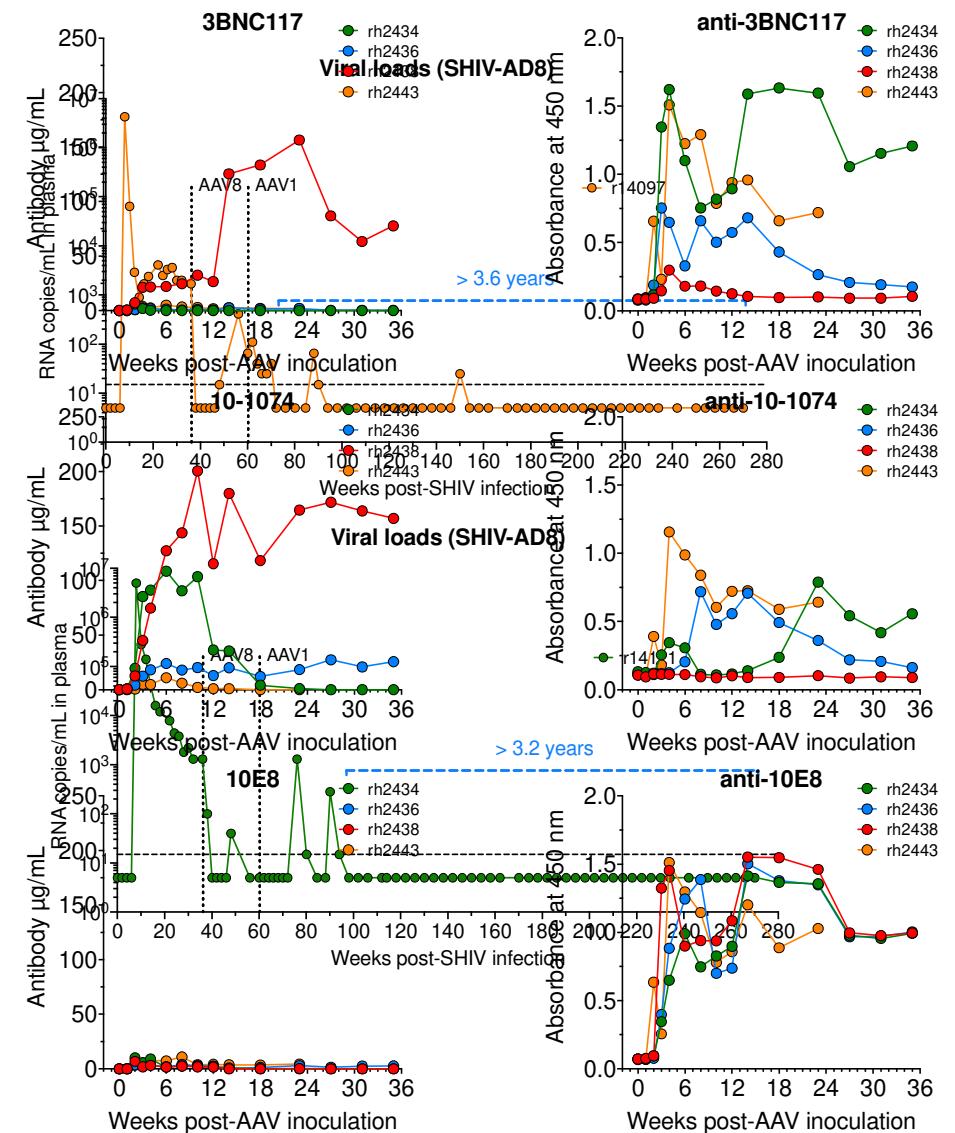

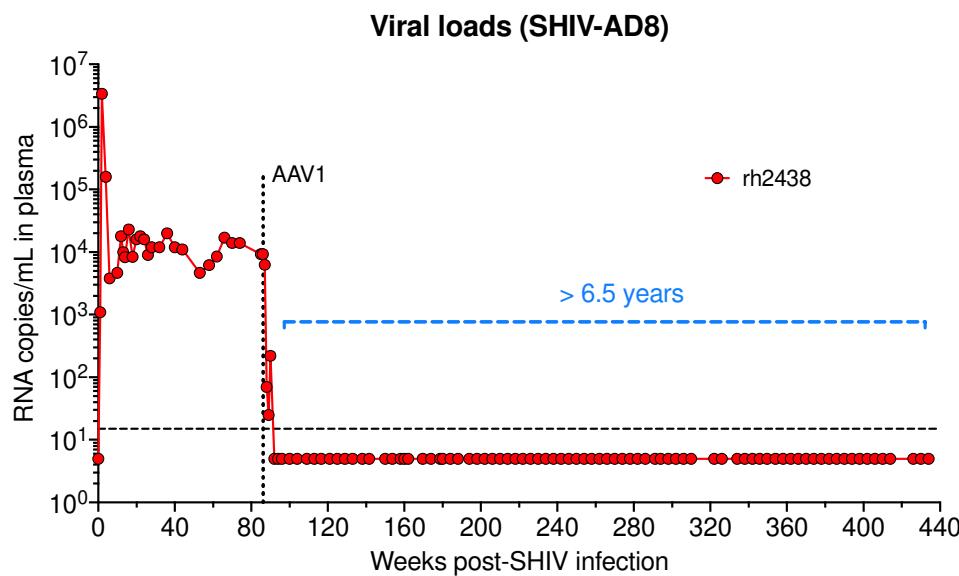

Image credit: CIRI / Nucleovir

AAV is a small virus which infects humans and other animals. AAV is not currently known to cause disease and is being exploited for gene therapy.

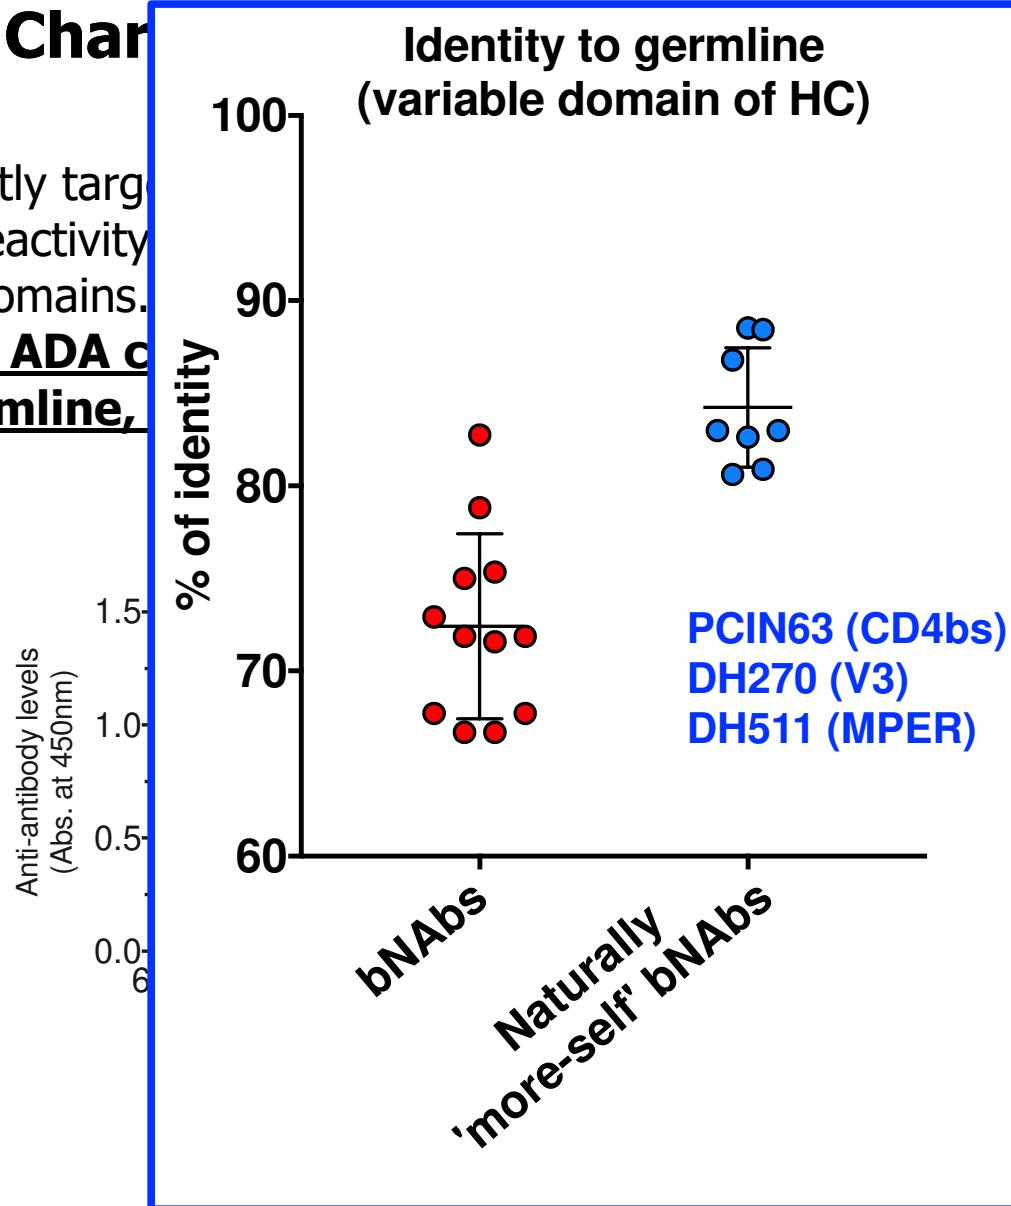

1. Circumvents the difficulties of generating a successful immunogen or vaccine.
2. Well characterized, broad and potent antibodies.
3. No need to produce large amounts of pharmaceutical grade antibody.
4. No need for repeated inoculations.
5. One administration could account for years of antibody expression.
6. Delivery of neutralizing antibodies with AAV is a promising approach for the prevention and treatment of HIV infection.

# Therapeutic use of AAV-delivered antibodies: promise & problems

## Characteristics:

1. ADAs mostly target CDR-H3
2. CDR-H3 reactivity is limited to variable domains.
3. Levels of ADA cross-reactivity from germline, measured by % identity to germline (variable domain of HC)

# Therapeutic use of AAV-delivered antibodies: promise & problems

# Conclusions

- 1. The use of closer-to-germline bNAbs may be a viable strategy for avoiding ADAs following gene therapy with AAV-bNAb vectors.**
- 2. Our data support the potential for long-term suppression of viral loads with the AAV-antibody approach but also highlight the difficulties associated with achieving such long-term suppression.**
- 3. Eradicating or minimizing ADA responses is crucial to make the AAV-delivery of antibodies a consistent and reliable approach against HIV.**
